Attempt : 1
Total Mark : 50
Marks Obtained : 40

Section 1 : Coding

1. Problem Statement

Imagine you are building a messaging application, and you want to know the length of the messages sent by the users. You need to create a program that calculates the length of a message using the built-in function `len()`.

Input Format

The input consists of a string representing the message.

Output Format

The output prints an integer representing the length of the entered message.

Refer to the sample output for formatting specifications.

Sample Test Case

Input: hello!!

Output: 7

Answer

```
# You are using Python
message = input()
print(len(message))
```

Status : Correct

Marks : 10/10

2. Problem Statement

Imagine you are developing a text analysis tool for a cybersecurity company. Your task is to create a function that analyzes input strings to categorize and count the characters into four categories: uppercase letters, lowercase letters, digits, and special characters. The company needs this tool to process log files and identify potential security threats.

Function Signature: `analyze_string(input_string)`

Input Format

The input consists of a single string (without space), which may include uppercase letters, lowercase letters, digits, and special characters.

Output Format

The first line contains an integer representing the count of uppercase letters in the format "Uppercase letters: [count]".

The second line contains an integer representing the count of lowercase letters in the format "Lowercase letters: [count]".

The third line contains an integer representing the count of digits in the format "Digits: [count]".

The fourth line contains an integer representing the count of special characters in the format "Special characters: [count]".

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: Hello123

Output: Uppercase letters: 1

Lowercase letters: 4

Digits: 3

Special characters: 0

Answer

Status : Skipped

Marks : 0/10

3. Problem Statement

Sneha is building a more advanced exponential calculator. She wants to implement a program that does the following:

Calculates the result of raising a given base to a specific exponent using Python's built-in `pow()` function. Displays all intermediate powers from base^1 to $\text{base}^{\text{exponent}}$ as a list. Calculates and displays the sum of these intermediate powers.

Help her build this program to automate her calculations.

Input Format

The input consists of line-separated two integer values representing base and exponent.

Output Format

The first line of the output prints the calculated result of raising the base to the exponent.

The second line prints a list of all powers from base^1 to $\text{base}^{\text{exponent}}$.

The third line prints the sum of all these powers.

Refer to the sample output for formatting specifications.

Sample Test Case

Input: 2

3

Output: 8

[2, 4, 8]

14

Answer

```
# You are using Python
```

```
base = int(input())
```

```
exponent = int(input())
```

```
result = pow(base, exponent)
```

```
powers_list = [pow(base, i) for i in range(1, exponent + 1)]
```

```
sum_of_powers = sum(powers_list)
```

```
print(result)
```

```
print(powers_list)
```

```
print(sum_of_powers)
```

Status : Correct

Marks : 10/10

4. Problem Statement

Implement a program that needs to identify Armstrong numbers.

Armstrong numbers are special numbers that are equal to the sum of their digits, each raised to the power of the number of digits in the number.

Write a function `is_armstrong_number(number)` that checks if a given number is an Armstrong number or not.

Function Signature: `armstrong_number(number)`

Input Format

The first line of the input consists of a single integer, n , representing the number to be checked.

Output Format

The output should consist of a single line that displays a message indicating whether the input number is an Armstrong number or not.

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: 153

Output: 153 is an Armstrong number.

Answer

```
def is_armstrong_number(number):  
    digits = [int(d) for d in str(number)]  
    power = len(digits)  
    armstrong_sum = sum(d ** power for d in digits)  
    return armstrong_sum == number
```

```
n = int(input())  
if is_armstrong_number(n):  
    print(f"{n} is an Armstrong number.")  
else:  
    print(f"{n} is not an Armstrong number.")
```

Status : Correct

Marks : 10/10

5. Problem Statement

Sara is developing a text-processing tool that checks if a given string starts with a specific character or substring. She needs to implement a function that accepts a string and a character (or substring), and returns True if the string starts with the provided character/substring, or False otherwise.

Write a program that uses a lambda function to help Sara perform this check.

Input Format

The first line contains a string `str` representing the main string to be checked.

The second line contains a string `n`, which is the character or substring to check if the main string starts with it.

Output Format

The first line of output prints "True" if the string starts with the given character/substring, otherwise prints "False".

Refer to the sample for the formatting specifications.

Sample Test Case

Input: Examly

e

Output: False

Answer

```
# You are using Python
```

```
main_string = input()
```

```
substring = input()
```

```
check_start = lambda s, sub: s.startswith(sub)
```

```
result = check_start(main_string, substring)
```

```
print(result)
```

Status : Correct

REC_Python_Week 3_CY

Attempt : 1
Total Mark : 30
Marks Obtained : 30

Section 1 : Coding

1. Problem Statement

You have two strings str1 and str2, both of equal length.

Write a Python program to concatenate the two strings such that the first character of str1 is followed by the first character of str2, the second character of str1 is followed by the second character of str2, and so on.

For example, if str1 is "abc" and str2 is "def", the output should be "adbecf".

Input Format

The input consists of two strings in each line.

Output Format

The output displays the concatenated string in the mentioned format.

Refer to the sample output for formatting specifications.

Sample Test Case

Input: abc

def

Output: adbecf

Answer

```
def concatenate_strings():  
    str1 = input().strip()  
    str2 = input().strip()  
    concatenated = []  
  
    for i in range(len(str1)):  
        concatenated.append(str1[i])  
        concatenated.append(str2[i])  
  
    result = ".join(concatenated)  
    print(result)
```

concatenate_strings()

Status : Correct

Marks : 10/10

2. Problem Statement

Emily is a data analyst working for a company that collects feedback from customers in the form of text messages. As part of her data validation tasks, Emily needs to perform two operations on each message:

Calculate the sum of all the digits mentioned in the message. If the sum of the digits is greater than 9, check whether the sum forms a palindrome number.

Your task is to help Emily automate this process by writing a program that extracts all digits from a given message, calculates their sum, and checks

if the sum is a palindrome if it is greater than 9.

Input Format

The input consists of a string *s*, representing the customer message, which may contain letters, digits, spaces, and other characters.

Output Format

The output prints an integer representing the sum of all digits in the string, followed by a space.

If the sum is greater than 9, print "Palindrome" if the sum is a palindrome, otherwise print "Not palindrome".

If the sum is less than or equal to 9, no palindrome check is required.

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: 12 books 4 pen

Output: 7

Answer

```
def check_palindrome(num):  
    return str(num) == str(num)[::-1]  
  
def process_message():  
    s = input().strip()  
    digit_sum = sum(int(char) for char in s if char.isdigit())  
    output = str(digit_sum) + "  
  
    if digit_sum > 9:  
        if check_palindrome(digit_sum):  
            output += "Palindrome"  
        else:  
            output += "Not palindrome"
```

```
print(output)
process_message()
```

Status : Correct

Marks : 10/10

3. Problem Statement

Raja needs a program that helps him manage his shopping list efficiently. The program should allow him to perform the following operations:

Add Items: Raja should be able to add multiple items to his shopping list at once. He will input a space-separated list of items, each item being a string.

Remove Item: Raja should be able to remove a specific item from his shopping list. He will input the item he wants to remove, and if it exists in the list, it will be removed. If the item is not found, the program should notify him.

Update List: Raja might realize he forgot to add some items initially. After removing unnecessary items, he should be able to update his list by adding more items. Similar to the initial input, he will provide a space-separated list of new items.

Input Format

The first line consists of the initial list of integers should be entered as space-separated values.

The second line consists of the element to be removed should be entered as a single integer value.

The third line consists of the new elements to be appended should be entered as space-separated values.

Output Format

The output displays the current state of Raja's shopping list after each operation. After adding items, removing items, and updating the list, the program prints the updated shopping list in the following format:

List1: [element1, element2, ... ,element_n]

List after removal: [element1, element2, ... ,element_n]

Final list: [element1, element2, ... ,element_n]".

If the item is not found in the removing item process, print the message
"Element not found in the list".

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: 1 2 3 4 5

3

6 7 8

Output: List1: [1, 2, 3, 4, 5]

List after removal: [1, 2, 4, 5]

Final list: [1, 2, 4, 5, 6, 7, 8]

Answer

```
def manage_shopping_list():  
    initial_list = list(map(int, input().strip().split()))  
    remove_item = int(input().strip())  
    new_items = list(map(int, input().strip().split()))
```

```
    print(f"List1: {initial_list}")
```

```
    if remove_item in initial_list:  
        initial_list.remove(remove_item)  
        print(f"List after removal: {initial_list}")  
    else:
```

```
print("Element not found in the list")  
initial_list.extend(new_items)  
print(f"Final list: {initial_list}")  
  
manage_shopping_list()
```
